

## Chapter 19: Chemical Thermodynamics

### Key Terms and Concepts:

#### Section I: Spontaneous Processes

**Spontaneous Process:** A process that occurs without outside intervention (e.g. An egg falling and breaking).

**Reversible Process:** A process where the change in the system can be completely restored by exactly reversing the change (e.g. Ice melting at 0°C). All spontaneous processes and processes at equilibrium are reversible.

**Irreversible Process:** A process where the change cannot be restored by simply reversing the change (e.g. the expansion of a gas in a vacuum).

#### Section II: Entropy and the Second Law of Thermodynamics

**Entropy (S):** A thermodynamic state function that expresses the randomness of a system. The more random or disordered the system, the greater the entropy of that system. The change in entropy, ( $\Delta S$ ) is equal to  $S_{\text{final}} - S_{\text{initial}}$ . In a reversible process at constant temperature, and  $q_{\text{rev}}$  represents the heat transferred in that process,  $\Delta S = q_{\text{rev}}/T$ .

**Isolated System:** A system that does not exchange energy or matter with its surroundings. Most of the time, we use isolated systems, and thus, unless otherwise indicated,  $\Delta S$  is equivalent to  $\Delta S_{\text{sys}}$ .

**The Second Law of Thermodynamics:** If  $\Delta S_{\text{univ}}$  denotes the total change in entropy of the universe, and  $\Delta S_{\text{sys}}$  and  $\Delta S_{\text{surr}}$  represent the change in entropy of the system and surroundings respectively, then the second law is as follows:

- For a reversible process,  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0$ . (in an isolated system,  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} = 0$ ).
- For an irreversible process,  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0$ . (in an isolated system,  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} > 0$ ).

This means that entropy is *not* conserved, and  $\Delta S_{\text{univ}}$  is continually increasing.

#### Section III: The Molecular Interpretation of Entropy

##### **Molecular Motion:**

- Translational – The entire molecule moves in space
- Vibrational – The atoms in the molecule move towards and away from each other periodically.
- Rotational – The molecules spin like a top.

The greater the molecular motion, the greater the entropy of a substance. As less energy is stored in the molecules, the entropy of those molecules decreases.

**The Third Law of Thermodynamics:** The entropy of a pure crystalline solid at 0K is 0. As the temperature increases, the entropy also increases, as shown. If  $W$  represents the number of possible arrangements for a substance, then  $S = k \cdot \ln(W)$ , where  $k$  is Boltzmann's constant, or  $1.38 \times 10^{-23}$ .

#### Section IV: Calculations of Entropy Changes

**Standard Molar Entropy (S°):** The molar entropy value of substances in their standard state (pure substance at 1 atm).

- They usually increase with number of atoms in the formula unit and molar mass
- S° of gases are greater than those of solids and liquids
- $\Delta S^\circ = \sum S^\circ(\text{products}) - \sum S^\circ(\text{reactants})$

#### Section V: Gibbs Free Energy

**Gibbs Free Energy:** A state function defined as  $G = H - TS$ , or  $\Delta G = \Delta H - T\Delta S$  for a reaction at constant temperature. For such a reaction at constant pressure; if  $\Delta G < 0$ , the reaction is spontaneous; if  $\Delta G = 0$ , the reaction is at equilibrium; if  $\Delta G > 0$ , the reverse reaction is spontaneous, but the surroundings must provide work for the forward reaction to occur. Free energy can also be defined as the energy available that a substance has to do work.

**Standard Free Energy of Formation (G°):** The free energy for a substance at a predefined state.

- $\Delta G^\circ = \sum G^\circ(\text{products}) - \sum G^\circ(\text{reactants})$  and  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$

#### Section VI: Free Energy and Temperature

**Effect of Temperature on Free Energy:** Enthalpy and Entropy are relatively unaffected by temperature, but depending on the reaction, the temperature could change the spontaneity of a reaction.

| $\Delta H$ | $\Delta S$ | $\Delta G$                                  | Example  |
|------------|------------|---|--|
| +          | +          | + at low temperature, - at high temperature | $2\text{HgO}_{(s)} \rightarrow 2\text{Hg}_{(l)} + \text{O}_{2(g)}$                   |
| +          | -          | + at all temperature                        | $3\text{O}_{2(g)} \rightarrow 2\text{O}_{3(g)}$                                      |
| -          | +          | - at all temperature                        | $2\text{H}_2\text{O}_{2(l)} \rightarrow 2\text{H}_2\text{O}_{(l)} + \text{O}_{2(g)}$ |
| -          | -          | - at low temperature, + at high temperature | $\text{NH}_{3(g)} + \text{HCl}_{(g)} \rightarrow \text{NH}_4\text{Cl}_{(s)}$         |

## Section VII: Free Energy and the Equilibrium Constant

- For all systems,  $\Delta G = \Delta G^\circ + RT \ln(Q)$ .  $\Delta G^\circ$  can be found through the calculated values, and  $Q$  is the reaction quotient for a system. The sign of  $\Delta G$  shows which reaction is spontaneous, the forward or the backward reaction
- If the system is at equilibrium, then the equation reduces to  $\Delta G^\circ = -RT \ln(K)$ , because  $\Delta G = 0$ , and  $Q = K$  at equilibrium.

### Sample Calculations:

-What is the entropy change when 50.0g of  $\text{Hg}_{(l)}$  freezes at normal freezing temperature ( $-38.9^\circ \text{C}$ ), if its molar enthalpy is 2.331 kJ/mol?

$$q = (50.0 \text{g Hg}) \cdot (1 \text{ mol Hg} / 200.59 \text{g Hg}) \cdot (1000 \text{J} / 1 \text{kJ}) \cdot (-2.331 \text{kJ} / \text{mol Hg}) = -581 \text{J}$$
$$\Delta S = q/T = (-581 \text{J}) / (243.3 \text{K}) = -2.48 \text{ J/K} \text{ (Since the process is reversible)}$$

- Calculate  $\Delta S^\circ$  for  $\text{N}_{2(g)} + 3\text{H}_{2(g)} \rightarrow 2\text{NH}_{3(g)}$

$$\Delta S^\circ = 2S^\circ(\text{NH}_3) - [S^\circ(\text{N}_2) + 3S^\circ(\text{H}_2)] = (2 \text{ mol})(192.5 \text{J/mol-K}) - [(1 \text{ mol})(191.5 \text{J/mol-K}) + (3 \text{ mol})(130.6 \text{J/mol-K})] = -198.3 \text{ J/K}$$

- Calculate  $\Delta G^\circ$  for  $\text{N}_{2(g)} + 3\text{H}_{2(g)} \rightarrow 2\text{NH}_{3(g)}$  at standard conditions

$$\Delta G^\circ = 2G^\circ(\text{NH}_3) - [G^\circ(\text{N}_2) + 3G^\circ(\text{H}_2)] = (2 \text{ mol})(-16.66 \text{kJ/mol}) - [(1 \text{ mol})(0 \text{kJ/mol}) + (3 \text{ mol})(0 \text{kJ/mol})] = -33.32 \text{ kJ}$$

- Calculate  $\Delta G^\circ$  for  $\text{N}_{2(g)} + 3\text{H}_{2(g)} \rightarrow 2\text{NH}_{3(g)}$  at  $500^\circ \text{C}$

$$\Delta H^\circ = -92.38 \text{kJ}; \quad \Delta S^\circ = -198.3 \text{ J/K} \text{ (calculated from the tables)}$$
$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -92.38 \text{kJ} - (773 \text{K})(-198.3 \text{ J/K})(1 \text{kJ} / 1000 \text{J}) = 61 \text{kJ}$$

- Calculate the boiling point of  $\text{CCl}_4$  using the values in the tables.

$$\Delta H^\circ = 32.6 \text{kJ}; \quad \Delta S^\circ = 95.0 \text{ J/K} \text{ (calculated from the tables)}$$
$$\Delta G^\circ = \Delta H^\circ - T_b \Delta S^\circ = 0 \text{ (since the system is at equilibrium if it is boiling)}$$
$$T_b = \Delta H^\circ / \Delta S^\circ = (32.6 \text{ kJ} / 95.0 \text{ J/K})(1000 \text{J} / 1 \text{kJ}) = 343 \text{ K} = 70^\circ \text{C}$$

- Calculate  $\Delta G^\circ$  for  $\text{N}_{2(g)} + 3\text{H}_{2(g)} \rightarrow 2\text{NH}_{3(g)}$  at 1.0 atm  $\text{N}_2$ , 3.0 atm  $\text{H}_2$ , and 0.50 atm  $\text{NH}_3$  and 298K

$$Q = (P_{\text{NH}_3})^2 / (P_{\text{N}_2})(P_{\text{H}_2})^3 = 9.3 \times 10^{-3}$$
$$\Delta G^\circ = -33.32 \text{kJ}$$
$$\Delta G = \Delta G^\circ + RT \ln(Q) = -33.32 \text{kJ} + (8.314 \text{J/mol-K})(298 \text{K})(1 \text{kJ} / 1000 \text{J})(\ln 9.3 \times 10^{-3}) = -44.9 \text{ kJ/mol}$$

- Calculate the equilibrium constant for  $\text{N}_{2(g)} + 3\text{H}_{2(g)} \rightarrow 2\text{NH}_{3(g)}$  using the standard free energies of formation

$$\Delta G^\circ = -33.32 \text{kJ}$$
$$\Delta G^\circ = -RT \ln(K)$$
$$-\Delta G^\circ / RT = -(-33,320 \text{ J/mol}) / [(8.314 \text{ J/mol-K})(298 \text{K})] = 13.4$$
$$K = e^{-\Delta G^\circ / RT} = e^{13.4} = 7 \times 10^5$$
